13. ABSTRACT (Maximum 200 words) <p>When comparing two population variances based upon sample data, one often uses a common statistical hypothesis test known as the F test. This test uses the ratio of the sample variances as a test statistic to determine if the population variances differ. The ratio is compared with a predetermined critical value that is dependent upon the sample sizes and the significance level of the test. The power of the test—that is, the probability of exceeding this critical value—can be determined a priori if one assumes to know the actual ratio of population variances. This report details the use of the F test and gives extensive tables of power for various significance levels, population variances ratios, and sample sizes under 100. It is hoped that this report will allow researchers to make wise choices of sample size in conducting future experiments of this type.</p>

1. INTRODUCTION

A problem that frequently arises in experimental studies is determining if the variance of a response variable for one population is greater than the variance of the same response variable for some second population. A sample question might be, "Based on the sample data, is the variation in tensile strength for Steel Lot A greater than the tensile strength variation of Steel Lot B?" The researcher must base his assessment on data collected from random samples from each population. Intuitively, it stands to reason that a correct decision is more likely to be made if the researcher is allowed to collect more data. Therefore, the probability of finding a true difference in population variances increases as one allows the sizes of the random samples to increase. This probability may be quantified if one assumes to know the true population variances. However, such an a priori evaluation of the experiment is not usually conducted.

This document is intended to be a reference manual for the power of the F test, a statistical procedure used to test whether or not one population variance is greater than another. The power of the test equals the probability of inferring from the sample data that one population variance is less than another. It is hoped that the enclosed tables will help test designers to choose appropriate sample sizes for studies in which population variances are to be compared.

2. STATISTICAL HYPOTHESIS TESTING

Determining if one population variance, σ_1^2 , is greater than another population variance, σ_2^2 , is an example of a statistical hypothesis test. In order to conduct such a test, a null hypothesis is postulated. The null hypothesis is an equivalence relationship involving the parameter(s) of interest which the experimenter tries to gather evidence against, and it is denoted by H_0 . In our case, the null hypothesis is $H_0: \sigma_1^2 = \sigma_2^2$. What we are looking to find in the data is conclusive evidence to support the claim that $\sigma_1^2 > \sigma_2^2$. This relationship is called the alternative hypothesis, and it is denoted by H_a . Alternative hypotheses may be either two-sided, for example $\sigma_1^2 \neq \sigma_2^2$, or they may be one-sided, as is the case with our problem. The choice of a one- or two-sided alternative hypothesis depends upon the researcher's prior beliefs concerning his parameter(s) of interest.

Because of the randomness associated with any experimental data, H_0 may be true and yet the observed data lead us to believe that H_a is true. In this case we have made an error, known as a Type I

error, in our inference. The probability of a Type I error is referred to as the significance level of the test and is denoted by the Greek letter " α ."

Likewise, the alternative hypothesis may be true; however, the data we collect might not be conclusive enough for us to infer so. In this instance, we fail to reject H_0 and make the other possible inferential error, which is known as a Type II error. The probability of a Type II error is denoted by the expression " $(1 - \beta)$." The term β is known as the power of the test, and it represents the probability of rejecting the null hypothesis in favor of the alternative hypothesis—a correct decision if H_a is true!

Naturally, one would like to minimize the chance of making either a Type I or Type II error. By attempting to minimize $(1 - \beta)$, we also try to maximize the power of the test. Table 1 provides a summary of the previous discussion.

Table 1. Possible Outcomes in Statistical Hypothesis Testing

		"The truth"	
		$H_0: \sigma_1^2 = \sigma_2^2$	$H_a: \sigma_2^2 < \sigma_1^2$
Conclusion based on the data collected	reject H_0 in favor of H_a	Type I error, made with probability α	correct decision, made with probability β (power)
	accept H_0	correct decision, made with probability $(1 - \alpha)$	Type II error, made with probability $(1 - \beta)$

3. THE F RATIO

When the response variable is assumed to be normally distributed (or approximately normally distributed), the F ratio is a test statistic used to determine if one population variance, σ_1^2 , is significantly greater than another population variance, σ_2^2 . Developed by R. A. Fischer at the beginning of the century, this is the most frequently used test statistic for comparing sample variances. The formula for the F ratio is given by $F = s_1^2 / s_2^2$, where each s_i^2 is the sample variance of the observations $\{x_{ij}\}$ ($j = 1, 2, \dots, n_i$) coming from a normal population with variance σ_i^2 . The sample variance formula is

$$s_i^2 = \frac{\sum_{j=1}^{n_i} (x_{ij} - \bar{x}_i)^2}{(n_i - 1)} .$$

The F ratio is a random variable having an F distribution with $v_1 = n_1 - 1$ numerator degrees of freedom and $v_2 = n_2 - 1$ denominator degrees of freedom. If F exceeds some critical value, F_C , then we conclude that the variance of the first population is greater than the variance of the second population. F_C is that value having an area of α to its right under the F distribution curve; that is

$$\frac{\Gamma[(v_1 + v_2)/2]}{\Gamma(v_1/2)\Gamma(v_2/2)} \left(\frac{v_1}{v_2}\right)^{v_1/2} \int_{F_C}^{\infty} \frac{x^{(v_1 - 2)/2} \partial x}{[1 + (v_1/v_2)x]^{(v_1 + v_2)/2}} = \alpha.$$

Preferably, the analyst selects α prior to the evaluation of the test statistic. Typical values of α range from 0.001 to 0.250 depending upon what the researcher considers "acceptable" risk for a Type I error. Once α is chosen, F_C is determined by iteratively solving the aforementioned equation or referring to tables of the F distribution found in many statistical textbooks.

Holding v_1 and v_2 constant, α and F_C are negatively correlated; that is, increasing α causes F_C to decrease, and vice versa. However, choosing a significance level that is too small has adverse consequences. While decreasing the significance level does give better protection against a Type I error, it reduces the power of the test by making rejection of H_0 more difficult when H_a is true. Thus, the significance level and the power of the test are positively correlated. The challenge to the analyst is to select a critical value, F_C , such that the significance level is low enough to afford adequate protection against a Type I error and the power is high enough to detect differences between σ_1^2 and σ_2^2 .

For fixed values of n_1 , n_2 , and α , the power depends only upon the value of the proportion σ_2 / σ_1 . Letting $\sigma_2 / \sigma_1 = k$, we see that

$$\beta = Pr(\text{rejecting } H_0 \text{ when } H_A \text{ is true})$$

$$\begin{aligned}
 &= Pr \left(\frac{s_1^2}{s_2^2} > F_C \right) \\
 &= Pr \left(\frac{s_1^2/\sigma_1^2}{s_2^2/\sigma_2^2} > \frac{1/\sigma_1^2}{1/\sigma_2^2} F_C \right) \\
 &= Pr \left(X > \frac{\sigma_2^2}{\sigma_1^2} F_C \right) \\
 &= Pr (X > k^2 F_C),
 \end{aligned}$$

where the random variable X has an F distribution with v_1 numerator degrees of freedom and v_2 denominator degrees of freedom.

4. POWER TABLES

The Appendix of this report consists of power tables for the test of hypothesis $H_0: \sigma_1^2 = \sigma_2^2$ vs. $H_a: \sigma_1^2 > \sigma_2^2$, for the following values of α , k , v_1 , and v_2 .

- 1) α (significance level): 0.01, 0.05, 0.10, and 0.25;
- 2) k (proportion σ_2 / σ_1): 0.30 to 0.60, in increments of 0.10; and 0.70 to 0.95, in increments of 0.05;
- 3) v_1 (numerator degrees of freedom): 5 to 8, in increments of 1; 10 to 20, in increments of 2; and 25 to 100, in increments of 5;
- 4) v_2 (denominator degrees of freedom): same values as v_1 .

Each set of facing pages corresponds to a specific value of α and k , found at the top of each table. Each row of a table corresponds to v_1 , while each column corresponds to v_2 . Table entries are the power of the one-sided F test calculated to three decimal places. Table entries were calculated using the SuperCalc5 spreadsheet and the following approximations to the F distribution.* In each case, X is a random variable having an F distribution with v_1 numerator degrees of freedom and v_2 denominator degrees of freedom.

Case 1 (v_1 even):

$$Pr(X > k^2 F_C) = \phi^{(v_2/2)} \left[1 + \frac{v_2}{2} (1 - \phi) + \frac{v_2(v_2 + 2)}{2 \cdot 4} (1 - \phi)^2 + \dots + \frac{v_2(v_2 + 2) \dots (v_2 + v_1 - 4)}{2 \cdot 4 \cdot \dots \cdot (v_1 - 2)} (1 - \phi)^{(v_1 - 2)/2} \right],$$

where

$$\phi = \frac{v_2}{v_2 + v_1 k^2 F_C};$$

Case 2 (v_2 even):

$$Pr(X > k^2 F_C) = 1 - (1 - \phi)^{(v_1/2)} \left[1 + \frac{v_1}{2} \phi + \frac{v_1(v_1 + 2)}{2 \cdot 4} \phi^2 + \dots + \frac{v_1(v_1 + 2) \dots (v_1 + v_2 - 4)}{2 \cdot 4 \cdot \dots \cdot (v_2 - 2)} \phi^{(v_2 - 2)/2} \right];$$

Case 3 (both v_1 and v_2 odd):

$$Pr(X > k^2 F_C) = 1 - A - B,$$

* Abramowitz, M., and I. A. Stegun. Handbook of Mathematical Functions, 6th printing, National Bureau of Standards, U.S. Department of Commerce, Washington, DC, 1967.

where

$$A = \begin{cases} \frac{2}{\pi} \left\{ \theta + \sin \theta \left[\cos \theta + \frac{2}{3} \cos^3 \theta + \dots + \frac{2 \cdot 4 \cdot \dots \cdot (v_2 - 3)}{3 \cdot 5 \cdot \dots \cdot (v_2 - 2)} \cos^{v_2 - 2} \theta \right] \right\}, & \text{for } v_2 > 1; \\ \frac{2\theta}{\pi}, & \text{for } v_2 = 1, \end{cases}$$

$$B = \begin{cases} \frac{2}{\sqrt{\pi}} \frac{\left(\frac{v_2 - 1}{2} \right)!}{\left(\frac{v_2 - 2}{2} \right)!} \sin \theta \cos^{v_2} \theta \left\{ 1 + \frac{v_2 + 1}{3} \sin^2 \theta + \frac{(v_2 + 1)(v_2 + 3)}{3 \cdot 5} \sin^4 \theta + \dots + \right. \\ \left. \frac{(v_2 + 1)(v_2 + 3) \dots (v_1 + v_2 - 4)}{3 \cdot 5 \cdot \dots \cdot (v_1 - 2)} \sin^{v_1 - 3} \theta \right\}, & \text{for } v_1 > 1; \\ 0, & \text{for } v_1 = 1, \end{cases}$$

and

$$\theta = \arctan \sqrt{\frac{v_1}{v_2} k^2 F_C}.$$

5. EXAMPLE

As an example of how to use the tables, consider an aerodynamics engineer who has made design modifications to a projectile. He believes that these changes can reduce the round-to-round dispersion by 25% and plans to fire 15 rounds of "old" ammunition and 15 rounds of the modified ammunition to test his conjecture. Because the modifications are inexpensive, he is willing to accept a 10% risk of

concluding that the round-to-round dispersion does decrease with his modification, even if there is no difference. If he is to use an F test to analyze his data, what is the power of the test for an actual 25% reduction in dispersion?

The significance level of the test is his probability of wrongfully concluding that the dispersions differ when they are equal, which we are told will be accepted as 10%; so $\alpha = 0.10$. Letting the first sample consist of "old" ammunition and the second sample consist of modified ammunition, the degrees of freedom are $v_1 = 14$ and $v_2 = 14$. If the actual reduction in dispersion is believed to 25%, then $k = \sigma_2 / \sigma_1 = 0.75$. Using the tables on pages 58 and 59 headed by $\alpha = 0.10$ and $\sigma_2 / \sigma_1 = 0.75$, we see that for $v_1 = 14$ and $v_2 = 14$, the power of the one-sided F test is 0.406.

If the engineer is dissatisfied with this value, he may increase the power of the test by either increasing alpha or increasing the sample sizes. Suppose now that the engineer wants the power of the test to be approximately 0.60 without changing the significance level. If he agrees to fire 31 rounds of the old ammunition, how many rounds of modified ammunition should be fired?

Referring to the same table ($\alpha = 0.10$, $k = 0.75$), we see that for $v_1 = 30$, a power of approximately 0.60 is obtained when $v_2 = 30$. Therefore, he should fire 31 rounds of the modified ammunition to achieve the desired power.

INTENTIONALLY LEFT BLANK.

USER EVALUATION SHEET/CHANGE OF ADDRESS

This Laboratory undertakes a continuing effort to improve the quality of the reports it publishes. Your comments/answers to the items/questions below will aid us in our efforts.

1. ARL Report Number ARL-TR-886 Date of Report October 1995
2. Date Report Received _____
3. Does this report satisfy a need? (Comment on purpose, related project, or other area of interest for which the report will be used.) _____

4. Specifically, how is the report being used? (Information source, design data, procedure, source of ideas, etc.) _____

5. Has the information in this report led to any quantitative savings as far as man-hours or dollars saved, operating costs avoided, or efficiencies achieved, etc? If so, please elaborate. _____

6. General Comments. What do you think should be changed to improve future reports? (Indicate changes to organization, technical content, format, etc.) _____

CURRENT ADDRESS

Organization

Name

Street or P.O. Box No.

City, State, Zip Code

7. If indicating a Change of Address or Address Correction, please provide the Current or Correct address above and the Old or Incorrect address below.

OLD ADDRESS

Organization

Name

Street or P.O. Box No.

City, State, Zip Code
